Bureau of Vital Statistics

SUMMARY FOR CALENDAR YEAR 1955

Introduction:

The 1955 vital statistics report appears as Part I of a two-part report entitled Public Health Statistics. Part II primarily contains morbidity data. The report has been divided in order to make easier distribution to groups interested primarily in one phase and yet keep the entire report intact for historical and research purposes.

The table format and contents in the 1955 report have been changed in several places from those in the six preceding reports. These changes reflect the increased interest of users. The bureau of Vital Statistics depends greatly on its readers for suggestions for table content and format. Readers are encouraged to inform the Bureau of their interests.

Included in this report are a number of critical comments concerning the use of vital statistics material. These comments are included as an aid to those who are confronted with a mass of tabular data and have little or no experience with their applications.

In the following pages are presented the beginnings of a long range plan to increase the value of the data. Several trend tables and charts have been included as a new feature. This long range approach is being developed because professional people, working with vital records as they are being filed, are in an excellent position to study them in their proper context and to evaluate the future needs for this data.

Beginning with this report for 1955, the plan of the Bureau is to follow this plan of presentation annually. By 1960 enough vital statistics data will be available so that full utilization can be made of the 1960 census.

The reader is referred to the previous report entitled Vital Statistics, State of Missouri, 1954 for a summary of the duties, activities and organization chart for the Bureau of Vital Statistics.

Compilation and Utilization of Vital Statistics:

Vital statistics in Missouri are compiled from six documents which are filed with the Division of Health by state law. To obtain the fullest use of these records, many sources of data must be utilized, including population, social science, medical, statistical, and demographic literature. Vital data are of little value unless special care is taken to analyze the cause and effect of the trends in vital events. To do this, knowledge and understanding of considerable background material are necessary. In Missouri, the six basic records on file with the Division of Health are: (1) birth records, (2) death records and (3) stillbirth records, each beginning with 1910, (4) marriage and (5) divorce records beginning with 1948, and (6) morbidity data. Much use is made of the data concerning vital events because it plays such an important part in both our economy and social structure. The births that

occur today will affect the sale of childrens' toys, the construction of schools, the number of homes to be built for future families and the aging population. People interested in these problems and others must turn to vital statistics for source and background data.

The economic and social factors which are affected by the occurrence of vital events, in turn, are significant in the present and future health of the people of Missouri.

The Reliability of the Data:

Statistics, using the word as a synonym for data, are neither more true nor more false than the interpretations given to them. Figures cannot be wrong until we interpret them as representing a specific thing. The value of the data lessens as the knowledge of the person using a specific kind of data decreases. The reports published by the Bureau of Vital Statistics are limited in their scope by the amount of time and money available for their publication. Therefore, they are published in a form largely standardized for use by vital statisticians. This means that certain facts must be realized if knowledge is to be gained from the use of these reports. The novice can best ask for advice from one trained in the use of statistics, their collection, tabulation, and interpretation. The sources of error found in vital statistics are under-registration; improper tabulating procedure; poor response or indifference on the part of those responsible for completing vital records; and probably the most dangerous source of error, improper interpretation.

Age and sex distribution together with social and economic conditions play a large part in the health of the people of a state. Missouri counties have a range in age from one county with one-half of its people under 21 years of age to another county with one-half of the people under 40 years of age. One interpreting vital statistics should realize that a county having a population composed primarily of younger persons might present a fictitious picture of good health if the number of deaths is used as a measure of health. The reverse of this situation could be true in a county composed predominantly of older persons.

Another example of how auxiliary data are important in vital statistics can be found in the interpretation of infant death rates. The number of infant deaths in Missouri is 29 deaths per thousand live births. In some small counties which have very few births this may represent a very small number of infant deaths per year. If a set of twins should also die in this county along with the usual number of infant deaths, the infant death rate could double for the year. But this higher rate is not alarming in such an unusual instance. Consideration of this kind should be given to events before alarm is spread and time and money is spent in needless effort.

Use of the Terms "Recorded" and "Resident":

Historically vital statistics have been presented in two forms, "Recorded" and "Resident". It is important to understand the significance of these terms

when analyzing vital statistics. As an example, this report shows birth data as follows for two selected areas:

Recorded live births, City of Springfield	2,935
Resident live births, City of Springfield	1,687
Recorded live births, Gasconade County	25
Resident live births, Gasconade County	181

What accounts for the differences in the above birth numbers? The differences seen in the figures above between the recorded and resident births of an area are due mainly to the facilities of the areas. In the first instance people are coming into a city to have their babies, because of the medical facilities available. In the second case people are leaving an area to have their babies because of a lack of medical facilities.

"Recorded" data are based on the number of vital events that occur in an area. These data are used to analyze events that might be affected by the place in which they occur.

"Resident" data are compiled for vital events that relate to persons residing in an area independent of where the events occurred. (A person is considered to be a resident of an area if he has resided there six months or more. In the case of live births, fetal deaths and infant deaths the residence of the mother is considered to be the residence of the child.) It is usually assumed that statistics based on these data reflect the social, economic and health conditions of the person's resident environment. In the case of births, it is assumed the mother intends to return to the area of her residence and thus she and her baby will affect the health conditions of that area. Ordinarily, a person's health is affected by the community in which he lives. However, in these days of a highly mobile population, the use of these figures is not as reliable as it once was. It is not always correct to charge the community where health problems become apparent with the total cause for these problems. An example in the use of resident and recorded information can be shown in the studies of infant deaths. If one is interested in the medical care given during delivery of a baby that later died, then one is interested in recorded data. If he is interested in the prenatal care given to this baby, then he requires resident data.

Births:

The excess of resident births over resident deaths in Missouri from 1950-1955 is 229,000 people. During the same period the population increase for the state amounted to 163,000 people. This means that Missouri lost 66,000 persons to other states during this time, or approximately 13,200 people annually.

Missouri's resident birth rate ranks 42 from the highest among the 48 states. This is a reflection of the older than average population in the state. The age distribution of the population of an area is affected largely (a) by the average number of children born to women of child-bearing age; and (b) by age selective migration across the area boundaries. In Missouri these two forces have worked together to produce an exceedingly high proportion of elderly persons. About one Missourian out of every ten is now 65 years of age and over. Only two states now have a higher proportion.

During the past several decades, not only has a large proportion of young people left the state each year, but until about 1950 the average number of children per mother has been declining. In addition to the steady emigration which is still continuing, there is a marked migration within the state from the rural sections to the larger cities and centers of industry. Table II shows the number of live births by residence for each county in the state for the period 1937 to date. Table III gives the corresponding information for deaths, exclusive of stillbirths. These tables are valuable for analyzing population movement, including the distribution of the population by age. These two tables should be combined with data available from the several decennial censuses in order to fully exploit their meaning.

Not only is the aging of the population greatly increasing the problems relating to the care of the aged, but the movement of the population to industrial centers is intensifying the public health problems. These are very important changes in the structure of our population and are causing an increasing tax burden on both the rural and urban communities. In the one case the need is to find revenue to aid the persons left behind and in the other to pay for the rapidly increasing needs for adequate facilities such as public health, fire and police protection, and schools.

It is estimated that near the year 1900 the number of births in Missouri exceeded 100,000, with a birth rate estimated near 32 per thousand population. The 1955 resident births in Missouri totaled 93,797 with a state rate of 22.7. This is the highest number of resident births in the state since 1910. If the present trend continues we may see very soon a resident live birth figure in Missouri of 95,000.

It must be remembered that the decrease in birth rate around 1935 lessened the number of young women of child-bearing age. To continue the present rate of birth in Missouri as well as in the United States, the family size must increase and the economic situation in the future must have the bright outlook it has had in the recent past.

Deaths:

In times past the cause of death was a very important instrument used to represent a reflection of Health conditions of an area. As communicable diseases lessened as a cause of death, the use of death statistics became less important as a reflector of the community's health. Today cause-of-death statistics are primarily useful for the larger population areas such as states and cities.

Causes of death can be useful in pinpointing "trouble spots" in public health. Many times those causes of death which are relatively few in comparison to diseases such as cancer and heart are in reality more important in an epidemiological program. Analysis of causes of death statistics should be maintained to see that the occasional case of diphtheria or typhoid fever, for example, is not in reality a focal point for a reservoir of infection. The death rate for a disease may appear minute in the total state picture, but the reappearance of the disease in the same area may be statistically significant, when the probability of such an event is realized. Any reservoir of infection can become serious if a general breakdown in sanitation should occur. This breakdown might occur during a fire, flood or war period.

As the average life expectancy at birth increases and the population becomes more mobile, deaths are not so apt to reflect a community's health

conditions. (The average life expectancy at birth in Missouri in 1950 was 67 years for males and 72.5 years for females. In 1900, the corresponding figures for the United States were 48 and 51. Separate data for Missouri are not available.) The final cause of death is a collective thing that reflects multiple causes and effects. The causes of death are a useful tool to use in chronic disease and other problems relating to the lengthening of the average life expectancy, particularly for measuring life expectancy after age 45. They are also useful in studying the health hazards associated with different types of work and can be used effectively in analysing the cause of accidents and other epidemiologic problems associated with accidents.

The ten leading causes of death in Missouri are listed in Table I. The diseases of the heart and circulatory system (330-334, 410-468)* accounted for 23,494 deaths or 55% of the total deaths in Missouri. Heart disease alone (410-443) accounted for 15,224 deaths or 35% of the total and cancer (140-205) accounted for 6,181 deaths or 14% of the total. There were 45 states in the United States with a lower death rate than Missouri in 1954. One explanation of the high death rate in Missouri is the older than average population of the state. It is important, however, to analyze these figures more closely and determine if this is the only cause.

Census data can be used to help in this analysis. During the census years much information can be gained regarding health problems and their relation to age and social characteristics. In many instances, ten years is too long to wait for data that are so important to the health of a state. Mobile population caused by shifting industry can create a health problem in a single year. For this reason, a census should be taken for the state at least every five years. But it is most important that this census be taken by an organization with the professional skill and experience necessary to conduct such a census. A poorly conducted census would create more problems than having none at all. Many worthless conclusions might be drawn if they were based on a poorly conducted census. However, much important information affecting production and marketing as well as the health and welfare of the people can be gained by a well conducted census of the state.

Marriage and Divorce:

Marriage and divorce statistics are collected from records that are filed by law with the Bureau of Vital Statistics. The central collection of marriage and divorce information is a rather new practice in the United States. Several of the larger states still do not maintain central files. Missouri has had a central registration since 1948.

These records are very valuable in public health and welfare programs. The family is the basic unit in a health program and the forming of new families through marriage or the dissolving of either new or old families by divorce presents many problems relating to the total health picture. The use of these statistics in a mental health program can be extremely useful for trend and cyclical data involving social change and adjustment periods, such as were brought on by the recent war. As more data are collected it is expected that the bureau of vital statistics will be called upon to furnish many special studies concerning marriage and divorce.

* Numbers in parentheses refer to code numbers in 6th Revision of International Statistical Classification of Causes of Death, 1948.

TRENDS IN MATERNAL DEATH RATES, INFANT DEATH RATES AND STILLBIRTH RATES
PER 1000 LIVE BIRTHS, BY COLOR: MISSOURI
1932 - 1955

Year	Stillbirth Rate		Infant Death Rate		Maternal Death Rate	
	White	Nonwhite	White	Nonwhite	White	Nonwhite
1932	38.4	98.1	53.9	113.6	5.9	10.8
1933	34.3	88.9	54.5	94.3	5.0	7.8
1934	31.3	73.9	59.4	107.6	5.5	11.0
1935	35.8	79.2	55.2	83.1	5.5	8.7
1936	33.4	74.7	55.7	90.0	6.0	8.5
1937	31.3	70.1	61.7	96.5	5.0	7.1
1938	32.0	76.4	48.1	93.0	3.7	6.1
1939	27.8	71.3	42.2	83.8	3.5	6.0
1940	29.8	69.5	44.7	78.4	3.5	5.7
1941	29.7	71.4	44.2	83.1	2.9	7.5
1942	26.2	65.0	37.1	64.8	2.3	3.8
1943	23.6	59.0	37.5	69.5	2.2	3.4
1944	23.3	59.8	35.1	63.7	1.8	5.1
1945	21.7	53.2	35.1	65.8	1.5	3.6
1946	21.4	51.2	31.1	55.8	1.2	3.7
1947	18.8	44.7	30.1	59.9	1.2	2.6
1948	18.7	42.7	28.6	49.3	.9	2.3
1949	17.5	35.9	28.7	43.4	.7	2.0
1950	17.2	37.2	27.1	49.0	.7	2.0
1951	16.4	34.3	25.8	45.0	.7	1.6
1952	16.1	29.7	25.9	49.4	.6	1.6
1953	15.9	33.1	25.4	46.9	.5	1.6
1954	15.8	27.7	24.2	46.6	.4	1.1
1955	14.7	29.8	23.1	41.7	.4	1.0

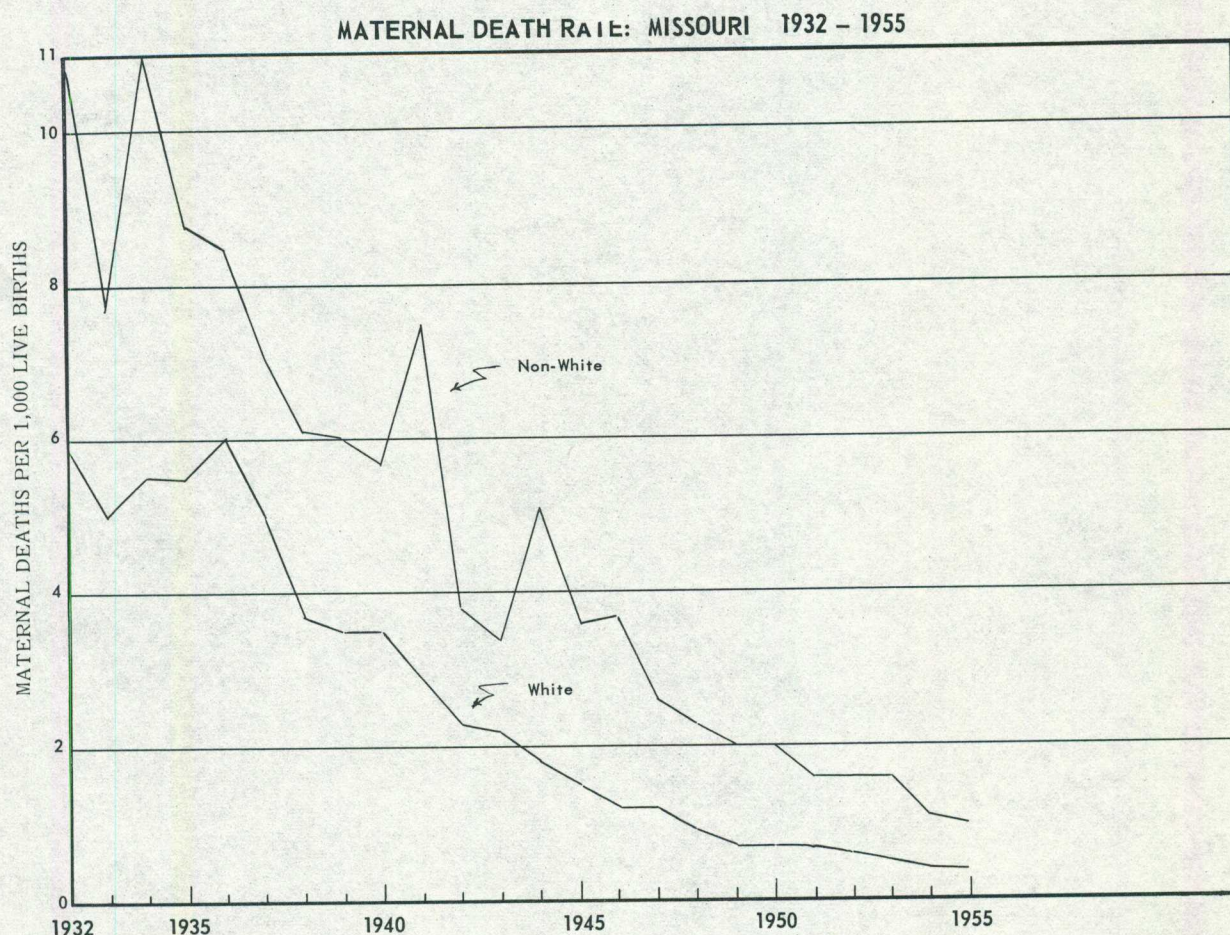

1932 - 1944 Recorded Data

1945 - 1955 Resident Data

Maternal Deaths:

In table H Maternal Deaths are classified by the cause of death. Maternal deaths in Missouri have been decreasing steadily in the last two decades. From figure 2, it can be seen that both the white and non-white rates are decreasing at about the same relative rate. The non-white rate is about at the point that the white rate appeared ten years ago, but the progress of the two is such that if the rates continue as they have in the past they should approach each other in the next five years.

Fig. 2

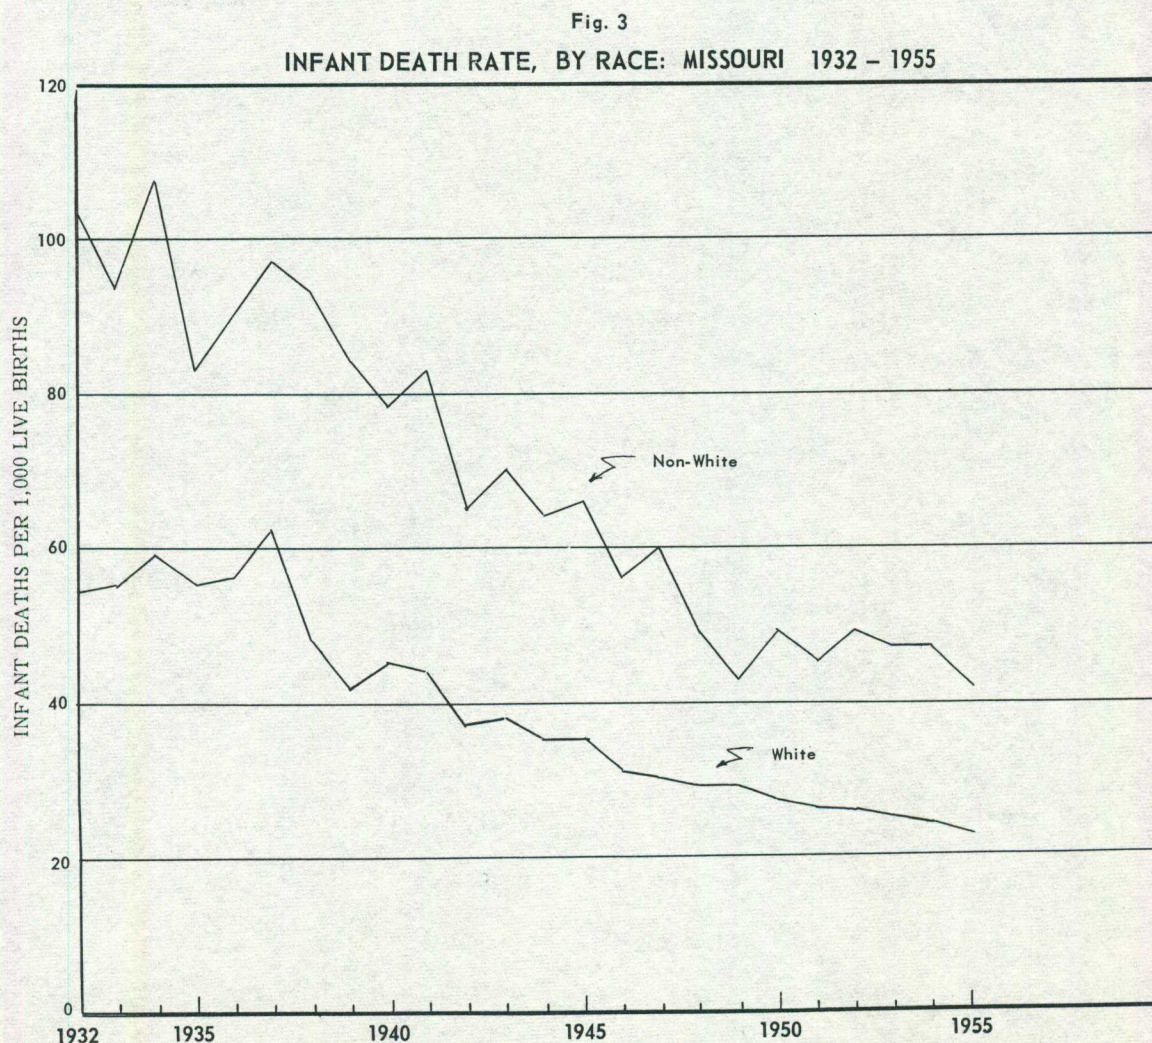

Infant Deaths:

Missouri's infant death rate has been decreasing steadily for the past ten years. When plotted on semi-logarithmic or ratio paper, it can be seen that there is little difference in the relative decline of white and non-white infant death rates. It appears as if the non-white deaths are still affected by environmental influences which could be due to social-economic characteristics. The white rate varies but little from year to year and appears to be rapidly leveling off. This could imply that the health conditions for infants may be reaching as favorable a level as may be expected for many years.

Malformations and prematurity account for 35 percent of all infant deaths (Table G.). In fact 38% of all infant deaths occur in the first hour of life and 64% occur in the first week of life. The difference between the proportion of white and non-white deaths in the first week of life, to the total deaths in the first year of life presents an interesting problem. The percentage of white children who die in the first week of life, of the total number of white children who die in the first year of life is 66%. The corresponding figure for non-white babies is 56%. Why is this so? Perhaps one reason is that white children generally have better prenatal care, which in turn could account for many live born babies that might have been born dead, thus increasing the percentage of live born babies that are below average in their ability to survive the first week. Or perhaps environmental conditions favoring survival of white children beyond the first week are better than among the non-white. When comparing races for a given characteristic as is done here, care must be taken to avoid confusing inherent racial differences with extrinsic factors such as housing and income.

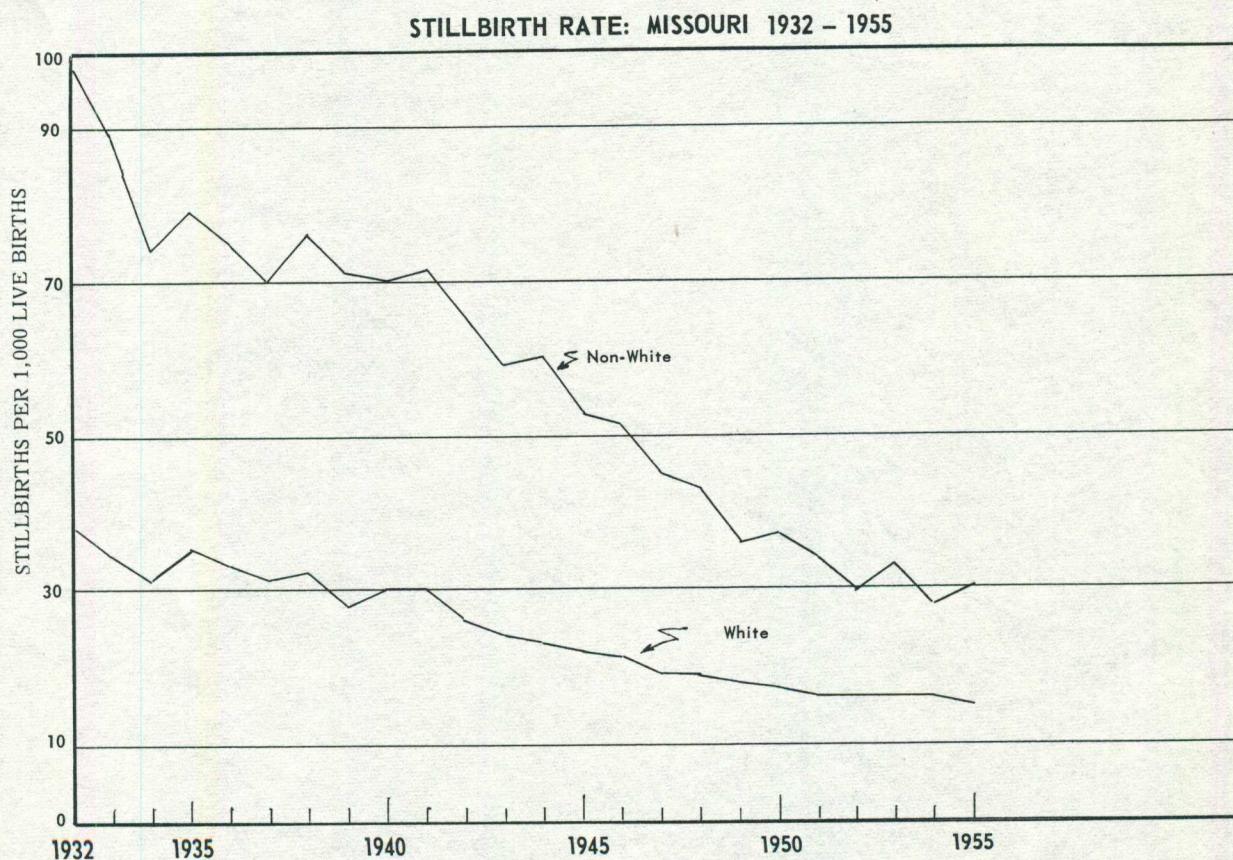

For further reduction in infant mortality, one must look into the prenatal history of the child and into delivery techniques, both in the hospital and in the home.

Stillbirths:

Figure 4 depicts the stillbirth rates in Missouri by white and non-white. The white rate has been declining steadily, but it appears that the greatest gains are being made in the non-white rate. One must interpret these charts with caution for at least two reasons can be given for this trend. One variable that might have caused this trend difference is an increase in the reporting of non-white births. This would tend to lower the non-white stillbirth rate if the number of actual stillbirths remained essentially the same. Another cause might be due to an increase in the non-white birth rate while the number of stillbirths reported remained about the same due to poor reporting practices. These two ideas seem to contradict each other, but point out how important it is to analyze vital records. The reporting of stillbirths is one of the weakest links in the entire registration chain. Until this is strengthened many babies will be lost due to our lack of knowledge as why a child is not born alive.

Fig. 4

Conclusion:

During the last ten years, there has been a major improvement in the quality of vital records filed with the Bureau of Vital Statistics. Not only has there been an increasingly higher percentage of completeness in filing of the six basic records, but there has also been a marked improvement in the completeness and accuracy of the data on the record itself. More and more persons are making extra efforts to prepare high quality records.

Some states and large cities are assisting in record management by providing training courses and seminars for local registrars of vital statistics, medical record librarians, physicians, and other closely identified with the preparation of the basic records. Such programs in Missouri are highly desirable.

Vital statistics in the past have been helpful in fighting disease; their help is needed still more in the future as the costs of public health rise. Today a more refined analysis of data must be made to meet the demands of our ever-increasingly complex society.

For the most effective results, vital data and vital statistics taken from them should always be studied in connection with other data in the subject field under investigation. They should not be taken out of context; doing so can lead to erroneous and unwarranted conclusions. The user of vital data must always be aware of the circumstances surrounding the collection and tabulation of the data he is using.

December, 1956

*The Bureau of Vital Statistics does not designate the following cities by population size.

CITIES 2,500-10,000

Berkley City
Breckenridge Hills
Brentwood
Florissant City
Glendale City
Hillsdale Village
Kinloch City
La Due City
Normandy
Pagedale City
Pinelawn City
Rock Hill City
St. Ann City
St. John's City
Shrewsbury City
Valley Park City
Wellston City

These cities are not included in the State Total figures which have been grouped by population size on the preceding pages.
